CHARACTERS OF SOME NEW SPECIES OF NORTH AMERICAN HEMIPTEROUS INSECTS, WITH ONE NEW GENUS

BY

EDWARD P. VAN DUZEE

Curator, Department of Entomology

1. Brochymena hoppingi, new species

Allied to affinis and with the same winged form of male genital segment, but with shorter head and shorter second antennal segment; nearly black with the pronotal margins roundedly crenulate. Length, male 12; female, 14 mm.

Male: Head slightly longer than broad across the eyes; cheeks overlapping tylus, sometimes almost contiguous at apex; subapical angle obtuse or rounded; second antennal segment two-thirds length of third. Sides of pronotum with about five rounded teeth on anterior lobe, the humeral lobe rounded anteriorly as in affinis but scarcely crenulate, humeral angle less prominent; surface deeply puntured and sculptured, the callosities more prominent than in affinis. Scutellum a little shorter, scarcely raised at base, median line subcarinate, surface more deeply pitted than in affinis. Elytra closely and quite evenly punctured with a few smooth calloused points. Rostrum passing middle of third ventral segment; venter nearly smooth with small, scattering obsolete punctures, sulcus shallow but obvious. Genital segment greatly extended either side as in affinis, their apices distinctly surpassing line of sixth abdominal segment, hind margin heavily bearded.

Color, mostly black, the testaceous interspaces less conspicuous, lateral crenulations of pronotum rufous; membrane with but few pale vermiculate marks; femora with pale subapical mark and median annulus more or less distinct; antennal incisures very narrowly rufous; connexivum with small marginal spots and the incisures rufous, the median line of the venter narrowly rufous.

Female: Larger with pale markings a little more conspicuous, especially near apex of scutellum and on venter.

Described from five male and five female examples taken by Mr. Ralph Hopping from beneath bark of a dead conifer in Vallecito, Co., Colorado, April 18, 1919. This species is quite distinct by its almost uniform dull black color. It differs from all our other species except affinis by the great lateral extension of the male genital segment.

It affords me pleasure to dedicate this interesting form to my friend, Mr. Ralph Hopping, in recognition of the valuable services he has rendered to entomology by his researches in forest insects.

Holotype, male, No. 749, and allotype, female, No. 750 Mus. Calif. Acad. Sci. A paratype, male, has been deposited in the Canadian National collection at Ottawa, at the request of Mr. Hopping. Other paratypes are in the Academy's collection.

Type locality, Vallecito County, Colorado.

2. Trichopepla pleyto, new species

Allied to californica but with broader pronotum and finer, concolorous punctures. Length 6 mm.

Head as in californica, with the cheeks more narrowed at apex and the whole surface more finely evenly punctured. Pronotum broader and flatter than in its ally, its width $2\frac{1}{3}$ times its greatest length (two times in californica), surface closely, finely punctured, omitting an irregular, incomplete, transverse vitta between the humeri, the callosities smooth; sides broadly expanded, flattened or slightly reflexed anteriorly, more oblique than in californica and slightly more arcuate; scutellum and elytra closely punctate. Antennæ, segment II a fourth longer than III and subequal to IV, V longest, II to IV becoming consecutively thicker. Rostrum attaining base of hind coxæ; segment II equal to III and IV together; osteolar canal long, flat and obtuse at apex. Male genital segment deeply excavated, its lateral angles truncate; this sinus in californica more shallow and trisinuate. Whole surface clothed with scattering long pale hairs.

Color, pale testaceous slightly varied with fulvous-brown, most conspicuous being a cloud on disk of corium, a short vitta either side on pronotum, a longer one within the lateral margins, a faint cloud either side on base of scutellum including a pale point, an indefinite vitta either side the pale median line of head and a narrow one within the margins of the cheeks. Usually there is a piceous cloud behind the calli and another on the anterior angle of pronotum. Beneath slightly clouded, but without distinct ventral vitta; tibiæ and tarsi a little darker; antennæ beyond middle of segment II blackish; membrane hyaline, showing the brown surface of the tergum; con-

nexivum indistinctly alternated.

Described from two males taken at Pleyto, Monterey Co., California, May 21, 1920, one male from Bradley, Monterey Co., May 17, 1920, and four from Bryson, Monterey Co., May 19, 1920. The finer, almost concolorous punc-

turation and broader flattened form give this insect much the aspect of a Carpocoris, but it has the longer osteolar canal of Trichopepla. Stål says this genus has the canal short and abrupt but this is true only when compared with such genera as Thyanta. He fails to compare his genus with Carpocoris with which it is closely allied.

Holotype, male, No. 751, and allotype, female, No. 752, Mus. Calif. Acad. Sci. Paratypes also are in the Academy's collection.

Type locality, Pleyto, Monterey Co., Calif.

3. Tollius quadratus, new species

Allied to setosus but with the antennæ more slender, the hairs clothing the body longer, the colors darker and more uniform, and the male claspers very differently formed. Length 9 mm.

Head obviously shorter and less produced before the eyes than in setosus. Antennæ more slender throughout with the first segment less incrassate than in the allied form and the fourth segment proportionately longer. Long hairs on the face arranged in three longitudinal bands as in the two allied species. Pronotum shorter than in setosus, its basal width one-fifth greater than the median length. Rostrum more slender, the basal segment nearly attaining base of gula (distinctly shorter in setosus), its apex reaching to the intermediate coxæ. Male claspers nearly quadrate, perhaps a little longer than broad, their inner margin converging somewhat apically and right-angled at apex, and armed with an almost terete projection at their outer angle which is nearly as long as the apical width of the clasper and a little oblique.

Color, grayish-brown, sparsely mottled with fuscous; vertex, neck and callosities infuscated; median line and sides of the face and two divergent vittæ on the neck dull castaneous; scutellum blackish with the basal angles and apex pale; membrane faintly mottled; beneath and legs dark castaneous varied with paler; tibiæ and tarsi, except at apex, pale; antennæ pale with first and fourth segments piceous beneath. Whole body evenly clothed with

long stiff black hairs and minute pale pubescence.

Described from one male taken by R. Mead at Monmouth, Fresno Co., California, late in August, 1915, and kindly sent to me for study by Dr. H. M. Parshley. The very characteristic male claspers with the shorter head and more slender antennæ makes the recognition of the male of this species a simple matter.

Holotype, male, No. 753, Mus. Calif. Acad. Sci. Type locality, Monmouth, Fresno Co., Calif.

4. Ischnodemus macer, new species

Allied to pracultus, a little longer with shorter rostrum and black sericeous venter; black, basal three segments of antenna, rostrum and legs fulvo-testaceous; elytra short, fuscous with pale costa and membrane. Length 4-6 mm.

Antennæ but little shorter than median line of head and pronotum together; segment I little longer than wide, attaining apex of tylus; II as long as anterior width of pronotum; III a little shorter than II, fusiform. Rostrum arched in all specimens before me but apparently reaching nearly to anterior coxæ; segment IV not longer than II; anterior femora more expanded than in falicus, its inner margin ciliate and armed at apical fourth with a short sharp tooth. Pronotum with a broad transverse minutely punctured area before the hind margin and an obvious sulcate median line on the anterior lobe. Elytra abbreviated, tip of corium attaining apex of first tergal segment; membrane ovate, reaching to middle of second segment, veins obscure.

Color, black, nearly opaque, clothed with minute sericeous scale-like pubescence and some longer gray hairs; hind margin of pronotum sometimes tinged with castaneous; antennæ, rostrum and legs fulvo-testaceous or at times almost castaneous; apical segment of antennæ black; elytra fuscous with costa pale yellowish and membrane white; connexival margins faintly

castaneous.

Described from one male and two female examples taken by Mr. A. Koebele at Nogales, Arizona, September, 1906. In my own collection is one male taken by the late Prof. F. H. Snow on the Santa Rita Mountains, Arizona, which differs only in having the hind margin of the pronotum castaneous. This specimen was listed by me as pracultus Dist. ?, in 1909 (Can. Ent., xli, p. 375) but it undoubtedly is distinct and specifically identical with those described above.

Holotype, male, No. 754, and allotype, female, No. 755, Mus. Calif. Acad. Sci. Paratype in Koebele collection.

Type locality, Nogales, Arizona.

5. Plinthisus martini, new species

Minute, piceous or black, moderately polished; hind margin of pronotum castaneous; antennæ at base, rostrum and legs, honey-yellow; brachypterous elytra truncate, with the corium and clavus connate, the latter confused punctate. Length scant 2 mm.

Head two-thirds as wide across the eyes as basal width of pronotum; eyes small, contiguous to pronotum; rostrum slender, attaining hind margin of metasternum; segment I attaining base of head, II and III subequal, each

longer than I. Antennæ slender; segment I scarcely surpassing apex of head, III and IV subequal, fusiform, and with the apex of II sparsely pilose. Pronotum about a fifth broader than long, moderately convex, minutely punctate near the hind margin; sides about parallel, very obsoletely sinuated posteriorly, carinate with a concentric groove beneath; anterior angles rounded. Elytra in type material brachypterous, truncate at apex, clavus and corium connate, their surface minutely confused punctate. Abdomen polished, minutely punctate; suture between third and fourth ventral segments straight and attaining margin of connexivum in female, slightly bent and becoming nearly obsolete on connexivum in male. Pleuræ polished, impunctate; osteolar canal slender, curved backward along hind margin of a broad opaque area. Anterior femora much dilated, unarmed, anterior tibiæ strongly curved and expanded at apex with the basal segment of its tarsus as long as the apical two together.

Color, head, pronotum and elytra piceous or almost black, the hind margin of pronotum slightly castaneous; abdomen brown, segment I and base of II

paler; rostrum and legs honey-yellow.

Described from five males and three females taken at Redwood Canyon, Contra Costa Co., Calif., February 11, 1920, from nests of wood rats, by Mr. J. O. Martin, to whom this species is gratefully dedicated. In addition, two male paratypes were taken by Mr. Martin from Berkeley hills, August 28, 1919. This tiny species is interesting in showing a difference between the sexes in the course of the suture between the third and fourth ventral segments. I am unable to detect the posterior opaque spot on fourth segment but probably it is distant from anterior if present at all.

Holotype, male, No. 756, and allotype, female, No. 757, Mus. Calif. Acad. Sci.; paratypes also in the Academy's collection.

Type locality, Redwood Canyon, Contra Costa Co., Calif.

6. Eremocoris semicinctus, new species

Aspect of obscurus but larger and rougher punctate with long-setose hind tibiæ and concolorous base of elytra bordered only with pale in male, anterior femora with large teeth. Length 9 mm.

Male: Head a little longer than broad across the eyes; bucculæ not attaining base of antennæ, segment I of antennæ passing clypeus by two-thirds its length; II a third longer than I; III two-thirds of II; IV two-thirds of III; rostrum attaining base of hind coxæ, segment I slightly passing base of head, II fully equal to III and IV together; mesosternal groove deep, the angular elevated sides forming a roughened tubercle; osteolar canal long, a little less than right-angled. Pronotum large, parallel, its length and width subequal; constriction shallow, at basal fifth; anterior lobe long, unusually convex, obscurely punctate, posterior flat, coarsely punctured; collum

linear, delimited by a row of punctures; explanate margins straight, narrow except across the constriction; hind margin broadly excavated. Scutellum broader than in obscurus: elytral punctures smaller than is usual; membrane complete. Anterior femora strongly incrassate, subsulcate beneath, the anterior edge armed with two large teeth, the apical the larger, and about three small ones either side the apical; anterior tibiæ much curved, armed with three teeth on the expanded apex, followed basally by about six small ones; hind tibiæ armed with numerous long erect stiff pale hairs.

Color, piceous black, becoming paler or more castaneous on antennæ, rostrum and legs, and slightly so on elytra, incisures of first antennal segment and base of second and third segments; tibiæ and tarsi honey-yellow; margin of pronotum for a space at middle and narrow costa to beyond tip of scutellum whitish; extreme tip of scutellum and spot on membrane at apex of corium

Female: Brachypterous, darker, more roughly punctured, especially on anterior lobe of pronotum.

Described from one male taken by Dr. E. C. Van Dyke, July 24, 1910, at Paradise Valley, Kings River Canyon, Fresno Co., Calif., at an elevation of 7,000 feet, one female taken by Dr. Van Dyke on Cypress Ridge, near Fairfax, Marin Co., Calif., May 29, 1920, and another female taken by the writer at Fairfax, May 11, 1919. This is a much larger species than, and very different looking from, the eastern ferus, our only other species having the hind tibiæ setose in both sexes.

Holotype, male, No. 758, and allotype, No. 759, Mus. Calif. Acad. Sci.; a paratype also in the Academy collection.

Type locality, Paradise Valley, King's River Canyon, Fresno Co., Calif.

Eremocoris dimidiatus, new species

Allied to ferus but larger and more parallel in form; elytra castaneous-brown with base abruptly pale. Length 7mm.

Head shorter than in ferus, minutely punctured either side beyond eyes; segment II of antennæ nearly twice as long as I; III three-fourths of II, IV a little shorter than III; rostrum reaching middle of metasternum, segment I just passing base of head, II shorter than III and IV together. Pronotum about as long as its humeral width; sides parallel with anterior angles rounded; constriction near basal fourth; anterior lobe polished, impunctate, strongly convex; collum narrow, linear, strongly differentiated by a line of punctures; posterior lobe flat, coarsely punctured; expanded sides rather broad. Scutellum long, depressed, remotely punctured and transversely wrinkled. Clavus with usual four rows of punctures, the second broken and connate with third at base; membrane reaching tip of abdomen in type; Carinate posterior margin of prosternum forming an angle or obtuse carina across base of median tooth which is much bent inward between anterior

coxæ; mesosternal sulcus deep, the tuberculate sides rough; osteolar canal broad and angled, the apex shorter than in allied species. Anterior femora shallowly sulcate beneath, the anterior edge with one large tooth and about five small ones either side, the basal larger; hind tibiæ with irregular long

hairs along its inner face, the outer surface nearly smooth.

Color, black, dull on the scutellum but more or less polished elsewhere; tip of tylus, basal segment of antennæ, rostrum and legs honey-yellow; segments II to IV of antennæ and anterior femora darker or piceous; collum and posterior lobe of pronotum castaneous, the latter with humeral angles and two oblique discal rays blackish; expanded pronotal margins whitish edged with fuscous; elytra testaceous to tip of scutellum, then abruptly fuscous-brown veined with castaneous; membrane brown with base and veins pale, both outer and inner angles with a large oval white spot; hind margin of metapleuræ, acetabulæ and genital segment castaneous.

Described from one male taken by me at Sunset, Colorado, July 19, 1903, at an elevation of 8,000 feet. This species has a longer, more pointed and flatter scutellum than obscurus and the hind tibiæ are ciliate within but bare in obscurus where also the pale basal portion of the elytra is shorter and does not include the clavus as it does in dimidatus. E. ferus has the anterior lobe of the pronotum flatter and opaque, the hind tibiæ entirely ciliate and the scutellum shorter.

Holotype, male, in collection of the author. Type locality, Sunset, Colorado.

8. Eremocoris opacus, new species

Shorter, broader and more opaque than in any of our other species. Length 6 mm.

Head a fourth broader across the eyes than long, shagreened but scarcely punctate, opaque at base, somewhat polished and clothed with appressed golden pubescence anterior to middle line of eyes. Basal segment of antennæ surpassing clypeus by a little more than half its length, segment II one-half longer than I; III and IV subequal, a little shorter than II. Pronotum almost a third wider than long, regularly narrowed anteriorly much as in ferus, moderately constricted at basal third, anterior lobe flattened as in ferus, nearly impunctate, dull black; collum narrow and distinct; expanded margins a little broader than in obscurus, armed by a single row of distant long hairs; posterior lobe coarsely punctured, hind edge less deeply excavated. Elytra more opaque than in obscurus, the expanded costa only a little polished; membrane complete, attaining apex of abdomen; scutellum a fourth broader than long; anterior femora of male about as in obscurus, armed with two strong teeth, the apical the larger, and about three small ones either side the apical large tooth; anterior tibiæ much curved and expanded at apex where there are two larger teeth and about four smaller ones placed basally from these; rostrum attaining middle of hind coxæ; segment I passing base of head, II subequal to III and IV together; mesosternal sulcus shallow, its sides scarcely tumid; osteolar canal right-angled; male genital segment feebly bi-tuberculate with a broad shallow apical sulcus.

Color, dull black becoming piceous or castaneous and polished on the an-

tennæ, legs, rostrum and venter, paler on the rostrum, tibiæ and tarsi, darker on the anterior femora and venter; collum, posterior lobe of pronotum, clavus and corium behind tip of scutellum castaneous somewhat varied with obscure brown; expanded lateral margins of pronotum to the tumid humeri and base of costa and corium creamy white; membrane fuscous with a large oval white spot at apex of corium and the base and nervures paler; surface clothed with sparse, short appressed golden pubescence.

Described from one male taken by me at Keen Camp in the San Jacinto Mountains, at 4,800 feet, June 8, 1917, and one male taken by Dr. Charles von Geldern at Cisco, Calif., in July, 1911. The broad form, short scutellum and opaque surface will distinguish this among our species with smooth hind tibiæ.

Holotype, male, No. 760, Mus. Calif. Acad. Sci.; a paratype, male (von Geldern specimen) also in Academy's collection.

Type locality, Keen Camp, San Jacinto Mountains, Calif., at 4,800 feet.

9. Megalocerœa koebelei, new species

Paler than debilis, with antennæ and legs more hairy and the clypeus less prominent; pale testaceous with slender rosaceous line behind the eye attaining hind margin of pronotum, and a similar one inferiorly on the sides of pectus and venter. Length $6\frac{1}{2}$ to 7 mm. to tip of venter.

Head as wide across the eyes as long from the basal constriction; a little narrowed behind the eyes so the latter do not quite touch the anterior angle of pronotum; vertex smooth, convex, slightly tumid above base of clypeus; median sulcus obsolete beyond the middle; clypeus very prominent and convex with deep sutures. Antennæ inserted close to anterior angle of eye; segment I as long as pronotum, cylindrical, becoming a little thinner on apical fourth; II nearly three times length of I and considerably thinner; III and IV successively thinner, III two-thirds length of II, IV one-half of III, I pale pilose, the hairs equal to thickness of III, II to IV subequal. Rostrum reaching on to second ventral segment, segment I attaining base of anterior coxæ. Pronotum two-thirds as long as wide, coarsely punctate; sides with a short obtuse carina behind collum, posteriorly ecarinate; callosities forming a narrow transverse ruga either side; median line obscurely carinate. Scutellum rugose-punctate, smooth at apex; basal lobe narrowly exposed, smooth. Elytra surpassing the abdomen, coarsely punctate, becoming smooth toward the costa. Male genital segment subacutely triangular; sinistral clasper slender, curved upward and acute at apex, the dextral short, blunt.

Color, yellowish luteous, a little deeper on head and scutellum; a longitudinal vitta behind the eye, fading out toward hind margin of pronotum, and another inferiorly nearly attaining apex of abdomen rosaceous or dark sanguineous, basal angles, depressed margins, and sometimes the median line of scutellum, sanguineous; antennæ rufous or rufo-piceous; tip of tibiæ and the tarsi blackish; eyes black; tergum with a sanguineous lateral vitta.

Described from one male and two female examples taken by Mr. A. Koebele at Nogales, Arizona, in September, 1906. This species should perhaps not be considered as congeneric with gracilis as the latter has the head longer and more depressed and the margins of the pronotum laminate, but in these respects debilis is nearly intermediate and is apparently more typical of the genus.

Named for Mr. A. Koebele who collected the specimens on which the description is based.

Holotype, male, No. 761, and allotype, female, No. 762, Mus. Calif. Acad. Sci.; a paratype in collection of Mr. Koebele.

Type locality, Nogales, Arizona.

10. Lygidea solivaga, new species

Smaller and paler than rubecula; color and aspect of a small Platylygus; fulvo-testaceous, in male marked with piceous on head and pronotum and tinged with rufous on elvtra. Length 5½ to 6 mm.

Male: Head vertical, produced below the eye for a space equal to threefourths length of eye; vertex much swollen, more prominent than in rubecula, polished, its base depressed and slenderly carinate; clypeus prominent, convex; rostrum somewhat surpassing hind coxæ. Pronotum shaped as in rubecula, the sides straight and ecarinate; surface more closely and finely punctate, Callosities prominent; scutellum minutely transversely rugose; vertex, pronotum and scutellum with a median smooth line indicated. Antennæ long, slender; segment I as long as head viewed from above; II 3½ times as long as I and nearly as thick, a little more slender at base; III and IV slender, together two-thirds length of II. IV nearly one-half of III. Elytra closely, minutely punctate. Sinistral male clasper small, but little wider at base, almost terete; dextral larger than sinistral, its superior angle somewhat produced and acute. Upper surface clothed with short, appressed pale hairs, more apparent on elytra.

Color, above fulvo-testaceous, paler on pronotum anteriorly and scutellum; head more fulvous with an oval piceous cloud either side anteriorly between the eyes; pronotum becoming fuscous toward sides and base, callosities polished black, collum and slender hind edge whitish, median line pale; scutellum with a brown cloud either side the pale median line, becoming piceous on basal lobe; elytra obscurely mottled with dull rufous, the apex of cuneus rufous; membrane faintly fuliginous with indications of a paler area at apex and smaller one either side; antennæ fuscous, segment I and immediate base of II and III pale; beneath piceous, polished, prosternum, margin of the pleuræ, osteolar region, coxæ and disk of venter yellowish; legs irrorate with rufous or brown, the base of femora pale.

Female: Fulvo-testaceous, almost uniform, base of pronotum more or less infuscated; antennæ slightly darker toward apex.

Described from four males and three females taken on pines on the summit of Mt. Eddy, Siskiyou Co., Calif., July 28, 1918.

Holotype, male, No. 763, and allotype, female, No. 764, Mus. Calif. Acad. Sci.; paratypes also in Academy's collection.

Type locality, summit of Mount Eddy, Siskiyou County, Calif.

11. Neoborus illitus, new species

Aspect of amænus scutellaris but still darker; black, shaded and varied with fulvous and brown. Length 5 ½ mm.

Head vertical, produced below the eye for a space equal to length of eye; eyes unusually narrow, but little wider above; vertex with a large polished paler spot either side; depressed base and a spot against either eye, punctate; base strongly carinate; disk with faint arcs and a median sulcus; clypeus smooth, polished, its base poorly distinguished; cheeks tumid; pronotum broader anteriorly and more convex than in amænus, shaped more as in Lygus; coarsely punctate, polished; callosities oblong, highly polished, sides carinate; scutellum with a few transverse dragged punctures; elytra closely punctate; rostrum attaining base of intermediate coxæ. Antennæ rather short; segment I a little shorter than distance between eyes; II slightly longer than width of head including eyes; III and IV together two-thirds length of II; IV two-fifths of III. Anterior angle of propleura below eye produced in a narrow rounded lobe above base of anterior coxæ. Sinistral clasper shaped as in amænus, strongly curved with a dorsal tooth at base.

Color, piceous black; collum and tumid inner cheeks polished whitish; vertex with a large fulvous spot either side; anterior submargin of pronotum, three rays on disk, and the slender hind edge yellowish; scutellum yellow, basal lobe black; elytra with a pale ray along median vein; base of cuneus broadly pale; membrane fuscous with whitish spot at apex of cuneus indicating a transverse band; prosternum, coxæ and disk of venter pale yellowish; antennæ fulvo-testaceous, infuscated on inner surface of segment I and base of II; legs pale with middle of femora and base of tibiæ fuscous. Pale

colors more extended in female.

Described from two males and nine females taken on ash trees at Fairfax, Marin Co., Calif., May 25, 1919. In form of pronotum allied to Lygus but the genital and most other characters indicate relationship with Neoborus. It shows much variation in extent of pale colors.

Holotype, male, No. 765, and allotype, female, No. 766, Mus. Calif. Acad. Sci.; paratypes also in Academy's collection.

Type locality, Fairfax, Marin Co., Calif.

12. Neoborus pacificus, new species

Allied to canadensis; uniformly whitish testaceous, with a black point on either pronotal callosity. Length 5 mm.

Male: Head vertical, produced below the eye for a space nearly equal to length of eye; clypeus strongly incurved below; cheeks tumid; vertex coarsely punctured with a spot against the inner angle of either eye and a concentric mark either side of middle line of vertex, anteriorly smooth; basal carina very slender; pronotum regularly, coarsely punctured, more convex than in canadensis; callosities small, transverse; sides ecarinate; collum and slender hind edge calloused and whitish; scutellum sparsely punctate, the edges smooth; elytra closely uniformly punctured; rostrum attaining posterior coxæ. Antennæ short; segment I a little longer than width of vertex between eyes; II about three times length of I; III nearly as long as I; IV a little shorter. Sinistral clasper shaped as in allied species but with the incurved apex longer and more slender and the basal tooth more prominent.

Color, uniformly testaceous, a little tinged with yellow, the punctures on head and pronotum more fulvous, the pale areas on vertex, collum, hind margin of pronotum and sides of scutellum whitish; callosities with round black dot at proximal end; antennæ slightly infuscated beyond the basal segment; tip of tarsi and a point on intermediate and posterior knees black; beneath tinged with fulvous with coxæ and disk of venter whitish; membrane faintly enfumed with pale lines along veins and spot on exterior

margin, the apex of areole with short brown line.

Female: Similar to male, without brown line at apex of areole.

Described from one male and two female examples taken at Corvallis, Oregon, July 31, 1900.

Holotype, male, No. 767, and allotype, female, No. 768, Mus. Calif. Acad. Sci.

Type locality, Corvallis, Oregon.

13. Neoborus viscicolus, new species

Allied to pacificus, but more tinged with fulvous and more uniformly punctured, without the smooth areas on the vertex found in that species. Length 3½ to 4½ mm.

Front and clypeus convex, more prominent than in pacificus, with deep impression at base of clypeus; vertex closely punctate with four flattish areas forming an arc anteriorly; front closely punctate with four smoother areas either side; cheeks as in canadensis, less prominent than in pacificus. Pronotum unusually convex, coarsely closely punctate, more finely about callosities, the latter prominent and distant but without indication of a longitudinal smooth line; scutellum tumidly convex and with the elytra coarsely and closely punctate; antennæ as in pacificus, but with segment II more slender; rostrum reaching hind margin of metasternum.

Color, a clearer and more fulvo-testaceous than in canadensis, almost uniform, a little paler beneath and somewhat darker on the head; proximal end of callosities in one example with a piceous point as in canadensis;

membrane faintly, almost uniformly fuliginous.

Described from two female specimens taken by me from mistletoe, *Phoradendron villosum*, growing on oaks at Sisson, California, July 24 and 26, 1918. The more convex form and different puncturation of head will distinguish this species from both *canadensis* and *pacificus*.

The paratype is larger and tinged with green on the abdomen and may be somewhat immature.

Holotype, female, No. 769, Mus. Calif. Acad. Sci.; the paratype also in Academy's collection.

Type locality, Sisson, Siskiyou County, Calif.

14. Dichrooscytus vittatus, new species

Allied to *irroratus*, but with a fuscous vitta across apex of corium, an oblique mark on inner angle of clavus, longer elytra and different male genitalia. Length 5 mm.

Head nearly vertical, more convex than in suspectus, about as in irroratus but with the vertex much broader; basal width of vertex subequal to length of pronotum in female, a little less in male, basal carina very feeble, the surface before it scarcely depressed; eyes much smaller than in irroratus; antennæ long, reaching to apex of cuneus; segment II four times length of I, subequal to the corium; III twice as long as IV, these together three-fourths of II; rostrum attaining apex of hind coxæ. Pronotum twice wider than long, nearly smooth, callosities small, distant; costal margin of elytra a little arcuate posteriorly, clothed with rather long prostrate pubescence; cuneus a little longer than its basal width. Sinistral male clasper broad for this genus, the two branches of nearly equal width, the ventral attaining apex of genital segment, broad and rounded at apex; dextral clasper short, rounded, with a minute hook at its dorsal angle.

Color, yellowish or greenish, more or less marked with sanguineous on the vertex, anterior lobe of pronotum, middle of scutellum and disk of corium; apex of corium with a rather broad transverse fuscous vitta, becoming sanguineous toward the costa; at inner angle of clavus a fuscous cloud which may be extended basally or even wanting; cuneus conspicuously pale, sulphuryellow, sanguineous at tip; membrane hyaline, slightly infuscated at apex with a darker spot at tip of cuneus and in apex of each areole. Beneath, with the antennæ, rostrum and legs including coxæ, paler or whitish; pleuræ and sides of venter washed with sanguineous; tip of rostrum and of tarsi black; tergum

sanguineous or blackish; tibial spines short, brown.

Described from two male and seven female examples taken by me at Huntington Lake, Fresno Co., Calif., July 27, 1919, at an elevation of 8,000 feet, one female from Colestin, Oregon, July 31, 1918, four females from Cayton, Shasta Co., Calif., July 14, 1918, and one pair taken at Fallen Leaf Lake, Eldorado Co., Calif., July 30, 1915. This is the species listed by me as *irroratus* in my report on

the Hemiptera of Lake Tahoe, but that species differs in wanting the fuscous markings on the elytra, in its narrower vertex and in the much longer and more pointed male clasper. I possess one specimen of what seems to be the true rufipennis Fallén, taken by me at Ward, Colorado, July 18, 1893, at an elevation of 9,500 feet, so that species should again be placed in our fauna. This specimen from Ward is a male and has the uniform coloration, fuscous vestiture, narrower vertex with weak basal carina and the smaller size of rufipennis.

Holotype, male, No. 770, and allotype, female, No. 771, Mus. Calif. Acad. Sci.; paratypes in the Academy's collection and in that of the author.

Type locality, Huntington Lake, Fresno County, Calif.

15. Coquillettia uhleri, new species

Aspect of *insignis*, longer and more slender, pale portions of elytra pale yellow, membrane almost entirely fuscous. Length 7 mm.

Head about as in *insignis*, produced beyond eye for a space about equal to greatest length of eye and to length of first antennal segment, subequal to width of vertex between eyes. Pronotum as in *insignis*, a little more than one-half as long as its basal width; scutellum almost equilateral; elytra nearly parallel, scarcely widened at apex of corium, distinctly so in *insignis*; tip of abdomen scarcely surpassing apex of corium; second antennal segment equal to sutural margin of clavus; III subequal to II, IV twice length of I; rostrum attaining apex of mesosternum.

Color, rufo-brunneus, clearer red on scutellum, anterior portion of pronotum and legs, tip of tibiæ and tarsi infuscated; elytra pale canary-yellow, the clavus, broad apex of corium, and extreme tip of cuneus, olive-brown; membrane uniformly infuscated with margin next cuneus narrowly white; antennæ and legs clothed with minute fuscous hairs; cheeks, coxæ and pleural

sutures a clearer red.

Described from one male taken by Mr. Fordyce Grinnell at Pasadena, Calif., May 29, 1909. In this species the apical fuscous band of the corium is a little shorter than the width of the corium at that point with its basal margin oblique, nearly parallel with the apical margin of the corium and quite broadly connecting with the fuscous of the clavus. This is the "variety" mentioned by Dr. Uhler in his description of insignis.

Holotype, in collection of the author.

Type locality, Pasadena, California.

Sericophanes noctuans Knight, I have taken at Soboba Springs in the San Jacinto Mountains, California, and at Cayton, Shasta Co., Calif. Mr. Knight was certainly right in placing this genus near Pilophorus. Another genus wrongly placed in the Halodapini in my catalogue is Dacerla which undoubtedly should go in Division Myrmecoraria near Mimoceps.

16. Coquillettia foxi, new species

Allied to *insignis*, but smaller, more slender and very distinct by the white elytra marked by a black band on apex of corium. Length scant 6 mm.

Head more porrect than in *insignis*, the gula and margin of bucculæ in nearly the same plane, quite strongly angled in allied species; segment I of antennæ scarcely longer than width of eye viewed from the side, less than width of vertex between eyes; II a little more than length of claval suture; length of pronotum about half its basal width; elytra distinctly but not strongly widened at apex of corium; tip of abdomen reaching nearly to apex

of cuneus; rostrum attaining intermediate coxæ.

Color, pale rufo-fulvous becoming clearer red on scutellum and beneath, the abdomen in the holotype piceous; antennæ infuscated with segment I and base of II paler; elytra white tinged with yellow on clavus, costal margin and middle of cuneus; apex of corium with a broad band of deep black which is one-half longer than width of corium at that point and is cut almost square across anteriorly at the apex of the clavus; cuneus white shading to pale yellow next the black apex; membrane infuscated on its apical half; tibæ and tarsi more or less infuscated, the posterior more strongly so; rostrum piceous on apical half; abdomen piceous, reddish at base with a pale band separating these portions.

Described from one male taken by Mr. C. L. Fox at Olancha, Inyo Co., Calif., June 5, 1917, and one male taken by Mr. J. O. Martin on the Mohave Desert, California, June 9, 1918.

I take pleasure in dedicating this distinct and pretty species to Mr. C. L. Fox in recognition of his valuable services in enlarging our knowledge of the insect fauna of California.

Holotype, male, No. 772, Mus. Calif. Acad. Sci.; a paratype also in the Academy's collection.

Type locality, Olancha, Inyo County, Calif.

The four species known to me may be separated by the following key:

Apex of corium and the clavus similarly colored.

Apex of corium deep black, clavus white.

1
foxi, new species.

 Apex of corium and clavus dark red, narrowly edged with black, base of corium silvery white. mimetica Osb.
 Apex of corium and clavus olive brown.

2. Pale portions of corium and cuneus yellowish, elytra scarcely widened apically, apical band of corium oblique anteriorly.

uhleri, new species

Pale portions of corium and cuneus white, elytra distinctly widened apically, apical band of corium nearly transverse anteriorily.

insignis Uhler.

Coquillettia balli Parshley is still unknown to me but probably is allied to amænus Uhler, a species I have never been able to recognize.

17. Lopidea taurina, new species

Aspect of *heidemanni*, but with a thicker head; bright sanguineous, darker along middle of elytra and on scutellum. Length 6 mm.

Surface moderately polished, sparsely clothed with very minute fuscous hairs; elytra scarcely wider apically; front unusually convex; base of vertex normally depressed. Antennæ long; segment I equal to width of vertex; II one-half longer than width of pronotum. Sides of pronotum feebly sinuated, the carinate edge extended entirely around the humeri to basal angle of scutellum; cuneus surpassing abdomen by more than half its length. Sinistral male clasper slender, the incurved apex forked; dextral clasper subterete for a distance of twice its width, then broadly bifurcate, the branches lying at a right angle with the stem and parallel with the apex of the genital segment, terete, acute at apex, and together forming three-fourths of a circle; dorsal spine of the pygofer abruptly incurved and very acute.

Color, bright sanguineous, becoming darker on head which has the usual black marks; callosities, antennæ, rostrum and legs black, pronotum posteriorly, scutellum and disk of the elytra more or less piceous or almost black; beneath largely infuscated or black, the propleura bright sanguineous; mem-

brane black .

Described from five males and six females taken by me at Colestin, Jackson Co., Oregon, August 1, 1918. In this very distinct species the dextral male clasper has much the shape found in *robiniæ* but the stem is slender and the two curved horns are subequal.

Holotype, male, No. 773, and allotype, female No. 774, Mus. Calif. Acad. Sci.; paratypes also in Academy's collection.

Type locality, Colestin, Jackson County, Oregon.

18. Lopidea bifurca, new species

Allied to marginata; yellowish brown, becoming clearer on the costal margin and cuneus. Length 5 ½ mm.

Surface a little polished, clothed with scattering minute white deciduous hairs; base of vertex flattened with an angular impression each side near the basal carina; sides of pronotum more sinuated with the humeral angles more prominent than in marginata; apical lobe of scutellum scarcely impressed at base; costa feebly arcuated. Sinistral male clasper broad, subtriangular, its abruptly incurved apex notched above and incised, with the ventral member blunt, the dorsal acute; dextral clasper very broad, slightly wider at apex, abruptly bent inward beyond the middle, the broad thin apex incised, having an acute tooth above and a squarish lobe below with its oblique apex recurved and minutely crenulate. In marginata the dextral clasper is longer and narrower, nearly parallel, with its apex oblique and entire or nearly so.

Color, pale fuscous-brown becoming yellowish along the costa and on anterior and lateral margins of pronotum; cuneus clear testaceous-yellow; membrane smoky, darker at base; head tinged with fulvous, base of vertex, a broad arcuate vitta either side on front and clypeus, black; antennæ black, rather slender, with basal segment much thicker; callosities black; legs pale brownish touched with fuscous on the femora, tip of tibiæ and tarsi; beneath varied with pale fuscous and brown, becoming whitish on the pleuræ and coxæ;

rostrum varied with black.

Described from 40 examples taken by me from a whitish weed growing along the railroad tracks at Colestin, Jackson Co., Oregon, August 1, 1918. This species has an immature look but this material is fully pigmented. Its dull colors match well the flower heads on which it lives.

Holotype, male, No. 775, and allotype, female, No. 776, Mus. Calif. Acad. Sci; paratypes in Academy's collection Type locality, Colestin, Jackson County, Oregon.

19. Lopidea puella, new species

Smaller than marginata; smoky brown, the costa narrowly and the cuneus entirely whitish. Length $4\frac{1}{2}$ mm.

Surface moderately polished, clothed with short black hairs and a few white scale-like hairs; front strongly convex, base of vertex feebly impressed; antennæ short, segment I half as long as width of vertex; segment II shorter than width of pronotum at base, angular impression between the collosities very deep; sides of pronotum feebly arcuated, the carinate edge carried around the rounded humeri to basal angles of scutellum; elytral costa scarcely arcuated. Sinistral male clasper broad, subovate; dextral subtriangular at base, its dorsal angle armed with an acute erect spine, apical member bent at right angles across the aperture of the segment, elongate triangular, obtuse. longitudinally furrowed.

Color, testaceous or smoky brown; callosities, antennæ and head black, the latter with the orbital margins and cheeks yellowish, sides and anterior mar-

gin of pronotum paler; narrow costal margins and cuneus whitish, the latter tinged with pink and edged with fuscous; membrane smoky black; legs blackish; lower surface blackish varied with reddish, the propleura whitish; gula and sternum black.

Described from three males taken by me at Bryson, Monterey Co., Calif., May 18, 1920. This is the smallest western species of Lopidea known to me and is quite distinct by its brown color with pale costal line and cuneus and the very distinct male genital characters.

Holotype, male, No. 777, Mus. Calif. Acad. Sci.; paratypes in collection of the Academy.

Type locality, Bryson, Monterey County, Calif.

20. Lopidea discreta, new species

A large dark red species allied to nigridea, but with the red coloring of heidemanni; male claspers much as in nigridea. Length 61/2 mm.

Surface moderately polished, sparsely clothed with oblique stiff black hairs as long as the thickness of the fourth antennal segment; segment II of antennæ a fifth longer than basal width of pronotum; sides of pronotum rectilinear. Sinistral male clasper small, linear, abruptly incurved at apex; dextral shaped much as in nigridea but broader and more sinuated ventrally with the vertical apical margin rectilinear, its lower (ventral) angle armed with two continguous teeth as long as their combined width; sinus at base of long apical spur with a short but distinct tooth.

Color, sanguineous; basal margin of pronotum, scutellum, clavus and corium as far as ulnar nervure much darker or even black; callosities, base of vertex, a double vitta on front, clypeus, sutures of cheeks, antennæ, rostrum, legs, pectus and venter in part black, the propleura bright red; membrane

deep fuscous.

Described from 24 specimens representing both sexes, taken at Huntington Lake, Fresno Co., Calif., during the last week of July, at an elevation of 7,000 feet. They occurred in numbers on elderberry bushes, on a blue-flowered lupine, and on a species of Vicia. It might be best to consider this a race or variety of nigridea, but it seems to me its characters on the whole are of specific value.

Holotype, male, No. 778, and allotype, female, No. 779, Mus. Calif. Acad. Sci.; paratypes in Academy's collection.

Type locality, Huntington Lake, Fresno County, Calif.

21. Lopidea nigridea hirta, new subspecies

Broader than nigridea, darker in color and more opaque and hairy with the antennæ thicker. Length 4½ mm.

Surface opaque, dull, clothed with short, stiff, black hairs and a few minute white scale-like hairs intermixed; costa quite distinctly arcuated; sides of pronotum moderately sinuated; segment II of antennæ about equal to basal width of pronotum; base of vertex feebly impressed. Dextral male clasper longer and slenderer than in nigridea, its apical margin minutely but quite evenly crenulate, not at all produced and lacinate at its ventral angle.

Color, dark brownish sanguineous, becoming clearer red on the pronotum and costal margin of corium, the cuneus still lighter sanguineous; head

marked as in typical form but less distinctly; callosities black.

Described from 29 examples representing both sexes, taken by me on San Miguel Island, Santa Barbara Co., Calif., May 20, 1919. The dark, opaque and hairy surface will best distinguish this subspecies.

Holotype, male, No. 780, and allotype, female, No. 781, Mus. Calif. Acad. Sci.; paratypes in collection of Academy.

Type locality, San Miguel Island, Santa Barbara County, Calif.

Under the name nigridea Uhler, I have placed a species commonly found on bushes in San Diego County and elsewhere in California, during May and June, which agrees exactly with Uhler's description except that segment II of the antennæ is as long as from the tip of scutellum to front of eyes, thus assuming a clerical error in the original description. In this species the dextral male clasper is broad, convex and strongly arched across the aperature of the genital segment, with its apex obliquely produced in a long acute spur which attains the dorsal line of the segment and is minutely serrated exteriorly; interior to the base of this spur is a shorter spine or tooth, sometimes minute.

22. Ceratocapsus apicatus, new species

Closely allied to fasciatus Uhl., but with thicker antennæ, a pale band across apex of corium as well as one at apex of scutellum, a unicolorous membrane and darker legs. Length 4½ to 5 mm.

Male: Head slightly more porrect and vertex more convex than in fasciatus; antennæ stouter throughout; segment II as long as III and IV together. Scutellum proportionately narrower than in fasciatus. Rostrum attaining apex of intermediate coxx; segment I attaining base of head. Apex of genital segment strongly subacutely produced, a little surpassing the valve; sinistral notch deep, abrupt, dextral shallow, sinuate; sinistral clasper small, forming a lobe at fundus of sinistral notch, dextral inconspicuous; plates long, produced for more than twice their basal width, rounded at apex. In fasciatus the ventral genital segment is short, truncate, not nearly attaining apex of valve; sinistral notch scarcely indicated, sinistral clasper long, acute at apex and curved to conform with apical margin of valve; dextral clasper ligulate, more than twice longer than wide, the plates short and subtriangular in form, with their apex rounded.

Color, castaneous-brown becoming paler on the head, pronotum and propleura and fuscous on antennæ beyond basal segment: elytra fuscous with a broad pale transverse band at apex of scutellum and a narrower one across apex of corium, leaving the intermediate fuscous band a little wider than basal pale band; cuneus and abdomen polished piceous black; membrane deep fuscous with black veins, faintly marked with a paler spot at apex of cuneus; in fasciatus there is a conspicuous pale band against apical margin of

cuneus. Legs castaneous.

Female: Broader behind, as in fascialus, the color paler anteriorly, sometimes with the corium almost entirely pale. In both sexes the upper surface is closely minutely punctured and clothed with short appressed pale hairs.

Described from 58 examples representing both sexes, taken from pine trees at Berkeley, Calif., September 29 and October 14, 1919, by Mr. J. O. Martin, and two females taken by me, one at Hoberg's Retreat, Lake Co., Calif., August 2, 1916, the other at Cayton, Shasta Co., Calif, July 15. 1918. This species could easily be confused with *fasciatus* but the thicker and darker antennæ, dark legs, black cuneus, darker membrane, narrower fuscous band on base of elytra, additional pale band at apex of corium and especially the very distinct male genital characters will distinguish the present species.

Holotype, male, No. 782, and allotype, female, No. 783, Mus. Calif. Acad. Sci.; and paratypes, all presented to the Academy by Mr. Martin.

Type locality, Berkeley, Calif.

23. Orthotylus dodgei, new species

Closely allied to pacificus Van D., separable by the blacker membrane and very different male genitalia; black, sides and abbreviated median vitta of pronotum, margins of elytra, and legs, yellowish. Length 6 imm.

Male: Head as in pacificus, the vertex flattened before the prominent basal carina; clypeus very prominent; segment II of antennæ rather longer than from tip of scutellum to apex of head, three times length of I. Pronotum as in pacificus, one-half wider than long; sides straight, carinate; surface transversely rugose behind the prominent callosities. Apex of abdomen attaining middle of cuneus. Surface clothed with rather long scattering pale hairs. Sinistral male clasper long, straight, somewhat clavate; dextral equally

long, parallel sided, flat, wider than hind tibiæ, somewhat incurved and sinuated with its apex abruptly bent upward in the same plane and truncate. Color, black; a line next eye from antennæ to base of vertex, interrupted a little before the base, a short line on anterior edge of pronotum, a broader vitta on basal lobe of pronotum and a similar one on each humeral margin, costal margin of corium, cuneus, rostrum and legs yellowish; knees with a dusky spot; apex of tarsi black; genital pieces partly pale. Female paler, with the antennæ mostly pale.

Described from two male and six female examples taken by me at Santa Cruz, Calif., June 3, 1919. This species could scarcely be distinguished from pacificus but for the very distinct male genitalia. Orthotylus pacificus, described from Victoria, B. C., I took at Northbend, Wash., July 9, 1920.

I am dedicating the present species to my friend Mr. E. A. Dodge of Santa Cruz, in recognition of his efficient work in the cause of entomology and of his courteous assistance to students of insects whose paths of effort are fortunate enough to meet his.

Holotype, male, No. 784, and allotype, female, No. 785, Mus. Calif. Acad. Sci.; paratypes also in the Academy's collection.

Type locality, Santa Cruz, Calif.

24. Orthotylus marginatus Uhler

A more careful study of my material in this species and dorsalis, in connection with additional specimens, has made it necessary to correct my former assignment of the males of these species. In his description of Cyrtorrhinus marginatus. Dr. Uhler has confused two species, a black form, margined with pale but wanting the pale median vitta on the pronotum and scutellum, and the species described below as serus in which this vitta is present and which Dr. Uhler mentions as a variation of marginatus. In my monograph of 1916, I placed this as a variation of dorsalis, and by some mishap, transferred the figure and description of the male claspers in these two species. The dextral clasper of marginatus, given as dorsalis (fig. 15), has its basal lobe too pointed. Better cuts of the claspers of these and related species will be published later. The true Orthotylus marginatus I have from Quinze Lake, Quebec, August 15, 1907, and Hamburg, N. Y., June 14, 1902. Like dorsalis, it is a willow feeder.

25. Orthotylus serus, new species

Closely related to marginatus Uhler, differing in having a pale median vitta from front of pronotum to tip of scutellum, the inner limit of the pale costal vitta straight, and in the form of the male claspers. Length 6 mm.

Vertex distinctly flattened before the obtuse basal carina, this flattening in marginatus very feeble; clypeus little prominent with feeble impression at its base; eyes, viewed from the side, reaching well toward the gula, in marginatus distinctly smaller. Pronotum as in marginatus, its length three-fifths its basal width; the callosities connected by an elevated area anteriorly which is scarcely apparent in marginatus; the posterior lobe nearly smooth, distinctly shagreened in marginatus. Rostrum attaining the hind coxæ, in marginatus not surpassing the intermediate. Dextral male clasper forming two squarish denticulate lobes, the ventral produced for about twice its width, with a truncate apex, its upper angle subacutely prominent; basal lobe squarish, broader than long and oblique at apex; sinistral clasper triangularly enlarged at tip with its apex obliquely truncate and its upper angle subacute; no basal appendage discernable.

Color, black and yellowish testaceous; above black, lateral and posterior margins of the vertex, broad median vitta from front edge of pronotum to tip of scutellum, and broad costal vitta on the elytra pale, the latter with a straight inner margin and enclosing toward its apex an obscure smoky cloud; cuneus fulvo-testaceous with a large fuscous cloud against its inner margin; membrane deep smoky with dark nervures and a pale spot at apex of cuneus, sometimes much reduced. Whole upper surface clothed with long pale decumbent hairs. Beneath black with a broad pale vitta, extended along the sternum to tip of venter in female; genital pieces largely pale; legs dusky testaceous with the tarsi embrowned; rostrum pale, black at tip; antennæ black.

Described from three male and ten female examples taken by me as follows: Hamburg, N. Y., July 1, 1911; Gowanda, N. Y., August 2, 1907; Colden, N. Y., July 7, 1901; Salamanca, N. Y., July 24, 1911. It lives on thorn bushes (Cratægus, species).

Holotype, male, and allotype, female, in collection of the author; paratypes in his collection and in that of the California Academy of Sciences.

Type locality, Hamburg, N. Y.

Genus Strophopoda, new genus

Aspect of a small Plagiognathus, but with an obtuse facial angle; allied to Chlamydatus with a narrower head and a distinct suture at base of tylus.

Head nearly vertical, with the eyes two-thirds basal width of pronotum, distinctly wider than median length of pronotum; vertex swollen, separated from base of clypeus by a distinct incised line; facial angle a right angle; eyes vertical, oval; gula short; rostrum passing intermediate coxæ, segment I reaching to base of head. Antennæ inserted near apical angle of eye; segment I attaining apex of clypeus; II as long as width of head with eyes, linear, a little thickened in male; III and IV together equal to II, III a third longer than IV. Pronotum transverse, its length one-half its basal width and equal to its apical width, sides straight or nearly so. Elytra long, almost parallel in male, the costa a little arcuated in female; tip of cuneus attaining apex of abdomen. Posterior femora much thickened; third segment of hind tarsi not longer than II, the suture very obscure. Surface smooth, polished, thickly clothed with short pale deciduous hairs.

Type of genus, Strophopoda aprica, new species. This genus was included in my keys to the genera of the Miridæ, 1916, but not before validated by description of a species.

26. Strophopoda aprica, new species

Black, polished, short pale-pubescent; antennæ and legs in part whitish, tip of cuneus and a connecting spot on membrane white. Length 2½ mm.

Characters as given for the genus; surface impunctate but minutely shagreened; male genital segment narrow, conical; sinistral clasper incurved and acute as in *Chlamydatus suavis*, the dextral broad, curved, truncate at

apex.

Color, deep black, polished; base of vertex with a pale median dot; antennæ pale yellowish in female, somewhat infuscated in male; segment I black, white at apex; II and III narrowly fuscous at base, more apparent in female; edge of bucculæ narrowly white; segment II of rostrum fuscous brown; apex of cuneus and a line on its basal fracture white; membrane with a white spot at tip of cuneus; femora black, tipped with white; tibiæ white, with spines and large dots at their bases black; tarsi brown.

Described from numerous examples of both sexes taken at various places in San Diego Co., Calif., from sea level to 3500 feet in the Cuyamaca Mountains, from April to October.

Holotype, male, and allotype, female, in collection of the author; paratypes in his collection and that of the California Academy of Sciences.

Type locality, San Diego County, Calif.

27. Chlamydatus monilipes, new species

Allied to suavis Reut., but with the antennæ mostly pale and the tibiæ dotted. Length 2½ mm.

Head with eyes about as wide as base of pronotum; vertex distinctly more convex than in suavis, with a nearly obsolete median sulcus; surface more dull and clothed with a shorter pubescence than in its ally. Male claspers formed as in suavis, the sinistral shorter and thicker.

Color, deep black, moderately polished; membrane uniformly infuscated; antennæ pale yellowish white becoming dusky on segments III and IV, basal two-thirds of I and narrow base of II black; femora black, tipped with white; tibiæ white strongly dotted with black at base of the black spines; tarsi whitish, the apical segment and claws blackish.

Described from seven males and three females taken by me at Alpine, San Diego Co., Calif., April 22, 1913. More recently Mr. Ralph Hopping has sent me a series of 15 taken by him at Mohave, Calif., May 3, 1919. Easily recognized by the pale antennæ and white legs with black femora and tibial dots. In this and the allied species the second antennal segment is thicker in the male.

Holotype, male, from Alpine, and allotype, female, in collection of author; paratypes in his collection and that of the California Academy of Sciences.

Type locality, Alpine, San Diego County Calif.

28. Merragata slossoni, new species

Narrower and paler than hebroides White, with the antennæ and legs more slender and less hirsute, apex of scutellum bifid. Length 13/4 mm.

Head more tumid on base of vertex than in hebroides, elevated above line of the ocelli by more than twice the diameter of the ocelli, the contour more convex when viewed from the side; above with a shallow median sulcus; antennæ nearly twice length of head as seen from above, segments I and II equal, I almost attaining apex of head, III shorter, IV fusiform, considerably longer and thicker than II but notably thinner than in hebroides; rostrum passing hind coxæ, segment I attaining anterior line of eye, II the anterior line of front coxæ, and III the middle of the mesosternum. Pronotum hardly twice wider than long, deeply constricted between the lobes, the median sulcus deep and passing anterior one-half of posterior lobe; collar distinct, distinguished behind by a line of deep punctures, a similar line following the posterior submargin, otherwise impunctate. Scutellum with a distinct median carine headly its average hind. lum with a distinct median carina basally, its apex obtusely bifid.

Color, pale castaneous becoming almost black on scutellum, vertex and mesoand meta-pleuræ, the middle of vertex broadly, and a large lobate spot covering much of the posterior lobe of pronotum, paler or fulvo-testaceous. Elytra pale at base, infuscated toward apex, claval area entirely and an interstitial line on the corium white; membrane pale fuscous with four white spots, one basal, one elongated, at apex, and one either side at apex of corium; antennæ and legs pale yellowish testaceous, the apical segment of the former darker; apex of tarsi infuscated, the claws pale; rostrum pale becoming blackish at apex; pronotum sparsely clothed with soft pale hairs; thickened portion of corium and vertex with soft white pubescence, the de-

pressions on pronotum and the pectus pruinose.

Described from one male taken at Biscayne Bay, Florida, by Mrs. Annie Trumbull Slosson, to whom I take pleasure in dedicating the species. The collection of the California Academy of Sciences contains four specimens of a species that agrees in every particular with Champion's description of hebroides White, taken on the hills back of Oakland, Calif., September 27, 1908. M. foveata Drake, is very close to hebroides but the white marks on the membrane are narrower, the general color is darker and the sulcus on the vertex has an obvious median longitudinal ridge. M. brunnea Drake is paler with the membrane almost uniformly whitish.

Holotype, male, in collection of the author. Type locality, Biscayne Bay, Florida.

29. Neæthus fragosus, new species

Related to grossus; longer with the front distinctly longer than broad and the costa much less arcuated toward the base; elytra subopaque as in grossus, the veins more or less infuscated. Length, male 5, female 6 mm.

Vertex transverse, oblong, on the median line a little more than one-half the length of the pronotum, its anterior margin very obscurely angled; front oblong, slightly wider at apex, its greatest length a fifth more than the width; clypeus with an obtuse median keel. Pronotum strongly produced anteriorly, much more so than in vitripennis. Elytra longer and narrower, than in grossus, in female 3½ by 5 mm., in grossus these measurements are 2½ by 3½ mm., opaque or slightly translucent, not at all transparent as in vitripennis; wings nearly as long as the elytra. Genital plates of male longer and more narrowed at the obtusely angled apex than in grossus.

Color, yellowish or greenish testaceous, in male usually becoming brownish on vertex and face, with a paler area on apex of front; veins of elytra

sometimes distinctly infuscated, especially in the male.

Described from six males and five females taken by me on the summit of Mt. Wilson near the observatory, October 18, 1917. This species is longer and narrower than grossus, with the females distinctly larger and paler than the males. In none of these types is there suggestion of the maculation found in typical grossus.

Holotype, male, No. 786, and allotype, female, No. 787, Mus. Calif. Acad. Sci.; paratypes also in the Academy's collection.

Type locality, summit of Mount Wilson, Pasadena, Calif.
